

The grid the lift and pressure figures were computed on

A different grid from the flow-field page, and a different shape of grid: an O-shape that closes around the wing rather than trailing behind it. All five calculations ran on this one grid: four with the slot open, blowing at different strengths, so the differences among those four come from the blowing alone; the fifth is a reference case with the slot closed. 39 984 cells, one cell deep, 10 mm span.

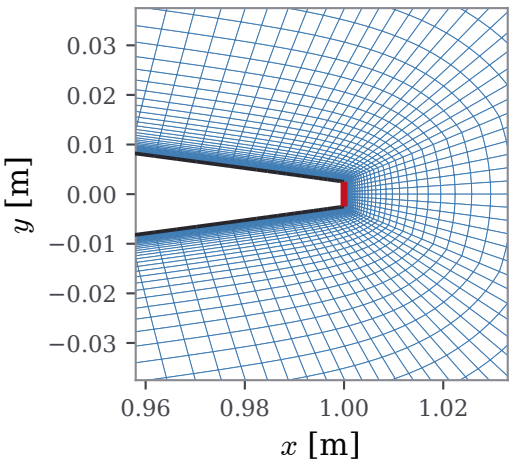

A. Around the wing (the whole grid reaches 26 m in every direction)

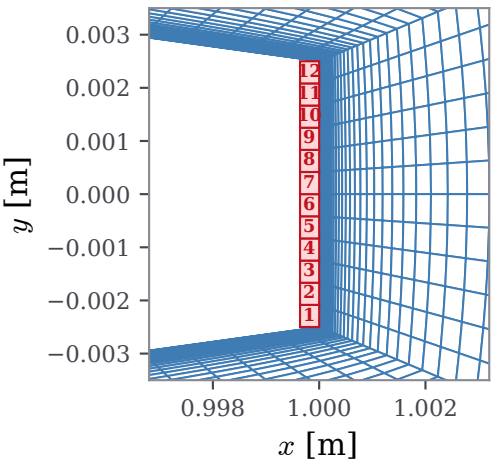

B. Leading edge

C. Trailing edge and the slot

D. Cells across the slot: 12

WHAT YOU ARE LOOKING AT

- Drawn cell by cell from the stored grid of the solved cases. No surface tessellation is used anywhere on this page.
- This grid is not the grid on the flow-field page. The two are shown on separate pages and never on shared axes.
- 12 cells span the 5.0 mm slot here as well, each 0.417 mm tall.

- Largest cell distortion 57.5°, largest skew 2.30, and no cell of zero or negative volume.
- Near-wall spacing rises with blowing, from largest 0.191 with the slot closed to largest 0.398 at the strongest jet. Every wall cell of every calculation is below the wall-resolved limit.
- None of the five calculations on this grid reached its convergence target; the lift they report had stopped moving.
