

A jet of air doing the job of a flap

WHAT YOU SHOULD KNOW ABOUT THESE NUMBERS

- This calculation ran its full 20000 of 20000 iterations and did NOT reach the convergence target fixed before it started. The pressure channel finished at $1.9\text{e-}04$ — about 191 times the 1×10^{-6} target. It fell early, then flattened and stayed flat.
- In this calculation the turbulence model's energy variable goes slightly negative in a handful of cells and is clipped back to zero on 99 % of iterations, continuously from iteration 91 to the last one. The picture below is HELD by that clipping, not converged free of it. It is a real limitation of this result.
- This is a different, finer mesh (46 180 cells) from the five calculations on the lift and pressure charts. It is shown here for the flow picture only and contributes no point to those charts. The two are never plotted on one axis.
- Indicative only. No mesh-refinement study, no experiment.
