

The grid the flow was actually computed on

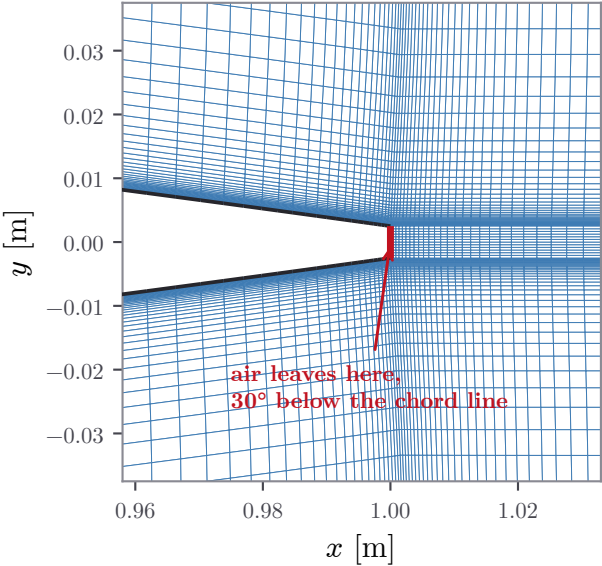

A. Around the wing and through the wake (the whole grid reaches 25 m in every direction)

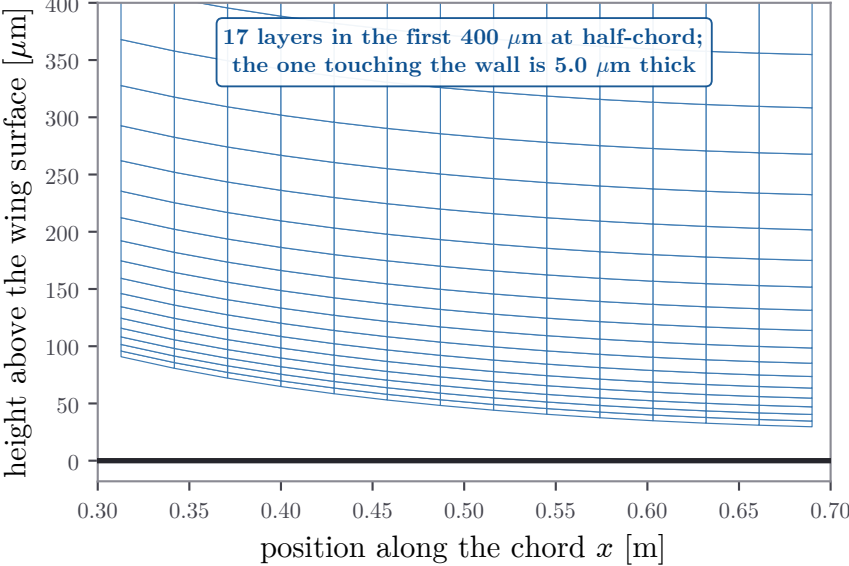

B. Leading edge

C. Trailing edge and the slot

D. The layers packed against the wall (height measured up from the surface)

Cell edges read back from the solved case: the whole grid, the leading edge, the slot and the wall layers.

Computer time for the calculation these near-wall numbers come from: we estimated 90.5 processor-minutes before running it and used 98.4 — 8.7 % over our estimate. Building the mesh itself took under one processor-minute.
