

How well the grid resolves the two places that matter

The slot is 5.0 mm tall — one two-hundredth of the chord — and the sheet of air it releases is the whole point of the design.
The other place that matters is the skin of the wing, where the drag is made. Both are counted here, not asserted.

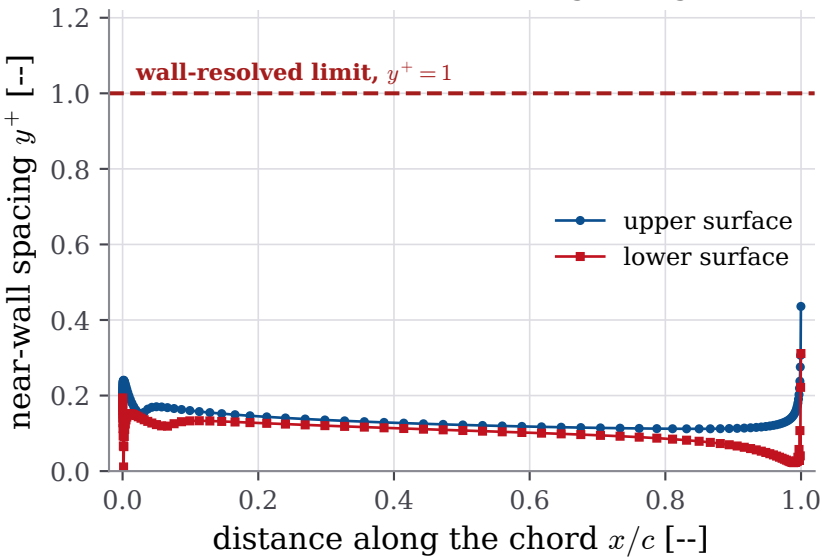

A. Cells across the slot, counted one by one

B. Near-wall spacing over the whole surface

C. Where the wall spacing is largest

D. Grid quality, as measured by the standard checking tool

measure	flow-field grid (46 180 cells)	force-sweep grid (39 984 cells)	target set before building	what it means
cells	46 180	39 984	--	every cell a six-sided box
cells across the slot	12	12	≥ 12	counted from the stored grid
largest cell distortion	33.6	57.5	< 65	angle between neighbouring cells, degrees
average cell distortion	7.2	10.0	--	degrees
largest cell skew	0.25	2.30	< 4	how far a face centre misses the line joining cell centres
cells of zero or negative volume	0	0	0	a single one invalidates a calculation
smallest cell volume [m ³]	1.00e-09	1.00e-11	> 0	--
largest cell stretch	1.61e+05	860	reported	length $\div$ thickness; large by design in the far wake

Both grids are made only of six-sided boxes; no cell was cut or collapsed. The stretch figure is large in the outer wake because cells are deliberately long there, in the flow direction, where nothing is changing across the flow — the stretching lies along the direction being resolved.

WHAT YOU SHOULD KNOW ABOUT THESE NUMBERS

- Panels B and C are properties of the grid and the solved flow together, so they are read from the calculation, not from the grid alone.
- All 200 wall cells sit below the wall-resolved limit (largest 0.436), so the flow next to the wall is computed rather than assumed from a formula.
- The near-wall spacing stopped moving well before the calculation ended: over the last 2 000 steps its largest value varies by 0.001 %.
- That calculation reached its step limit before it met its convergence target, so its flow field should be read as indicative.
- Panel D sets two different grids beside each other in one table. They are never drawn on shared axes.
