

Solid-body temperature monitors, replayed from the sixteen runs
upper trace: hottest point in the housing; lower trace: coldest point; band between them

Every trace is the run's own monitor output, sampled every 100 iterations and replayed unchanged. The monitor scans the housing cells AND its bounding faces, so its settled value sits 0.0150 K above the cell-only peak quoted in the map table at the hottest point - both are real readings of the same solution.
