

Radial temperature cut through the hottest solid cell $P = 305 \text{ W}$, $U_\infty = 10 \text{ m s}^{-1}$, axial station $z = 124.55 \text{ mm}$
 radius axis broken at the two material interfaces so the 3.5 mm housing wall is visible; every panel is linear in r and every marker is one computational cell

THREE MATERIAL REGIONS, THREE DISTINCT MEAN SLOPES ($-0.1500 / -0.0290 / -0.3221 \text{ K mm}^{-1}$) - but only the housing wall is a straight line.

The rotor core carries a volumetric heat source and the air carries a thermal boundary layer, so both are curved; their single slopes are region averages and are labelled as such.
