

The grid the flow was actually computed on

Every line below is an edge of a real computation cell, read back out of the solved case. This is the grid the equations were solved on — not a drawing of the shape, and not the triangles of the CAD surface. C-shaped grid wrapped round the wing and trailed downstream: 46 180 cells, one cell deep, 1.0 m span.

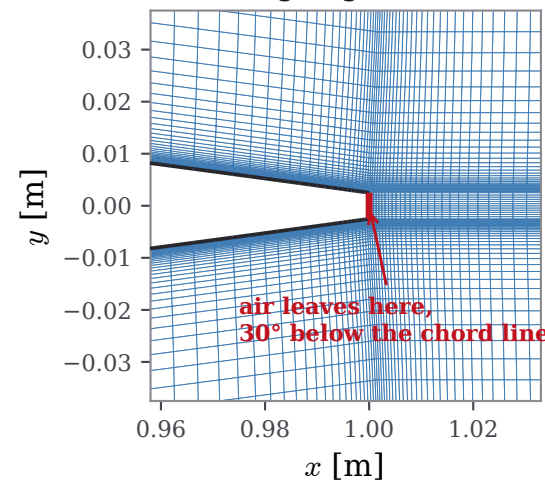

A. Around the wing and through the wake (the whole grid reaches 25 m in every direction)

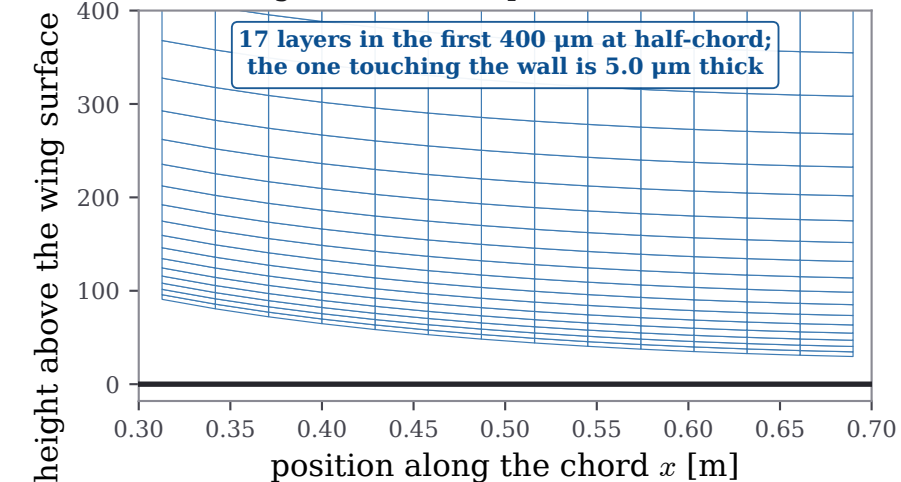

B. Leading edge

C. Trailing edge and the slot

D. The layers packed against the wall (height measured up from the surface)

WHAT YOU ARE LOOKING AT

- Every panel is drawn cell by cell from the stored grid of the solved case. No surface tessellation is used anywhere on this page.
- The wing outline is drawn from the wall faces of the grid itself, so the outline and the cells cannot disagree.
- Panel D measures height up from the surface rather than from the centreline. At true proportions the layers next to the wall are far too thin to see: the first is 5 μm against a 1 m chord.

- The refined wake region is refinement along the flow direction: cell length grows by no more than 8 % from one cell to the next out to 3 chords, then relaxes toward the far boundary.
- This is a two-dimensional calculation. The grid is one cell deep and the two side faces take no part in the solution.
